(54) Title: ROUTING SYSTEMS AND METHODS FOR IMPLEMENTING ROUTING POLICY

(57) Abstract: In some embodiments, a method and routing system parameterize a routing policy and apply the parameterized-routing policy to a route. Parameters are assigned to at least some policy statements of the policy. The parameterized policy may be called with parameters stored in a parameter table. In some embodiments, common blocks of the policy may be identified and assigned parameter sets. A commonized routing policy may be reused within more than one policy. In some embodiments, a method and routing system may evaluate a configuration file to determine relationships between route attributes. The relationships may be expressed in one or more mathematical functions, and when a route is received from a peer, the attributes of the route may be modified based on the mathematical functions. In some embodiments, a router and method for implementing routing policy and traffic engineering are provided. Routing policy may be implemented by performing a policy translation on a policy configuration to generate an internal-policy representation. Attribute-operator pairings of the internal-policy representation may be verified with one or more client dynamic load libraries (DLLs). When the attribute-operator pairings have been verified, the internal-policy representation may be compiled and stored in a system database. A client protocol may be notified that the routing policy has been modified.

## ROUTING SYSTEMS AND METHODS FOR IMPLEMENTING ROUTING POLICY

5

### Technical Field

Embodiments of the present invention pertain to routers and routing systems, and in particular, to routing policy and routing-policy configuration.

### Background

Routing systems use configuration files and routing policy to make  
10 decisions regarding routes. Configuration files are used to apply policy to routes  
which may be received as new routes or as part of route-update messages.  
Conventional configuration files are growing very large and very complex with  
the advent of larger and more sophisticated routing systems. Conventional  
configurations may take many lines of configuration to effect a desired result.  
15 One problem with these large configuration files is that the need to vary a single  
value in the configuration may require a whole block of lines to be repeated  
many times in the configuration file. This makes for extremely large amounts of  
configuration that are replicated, maintained, stored, and processed. These large  
configuration files must also be understood by the device and the user. Thus  
20 there are general needs for improving router-policy configuration. There are also  
needs for reducing the amount of configuration. There are also needs for  
reducing the amount of configuration for specific routing policies, especially  
when only a few values are varied within the configuration.

There are times when a user or operator may wish to evaluate additional  
25 information on a running network. One problem with conventional routing  
systems is that conventional systems inhibit direct access to information outside  
of the route attributes. This makes it difficult for a user or system administrator  
to create routing policies, for example, that take into account traffic statistics on  
a running network when altering route attributes. Thus, there are needs for  
30 systems and methods that may allow a user or system administrator to  
incorporate additional non-route attribute information, such as traffic statistics,

into a running network. There are also general needs for routing systems and methods that may implement routing policy using non-route attribute data such as traffic engineering information.

#### Summary

5           In some embodiments, parameterization is applied to routing policy and routing-policy configuration. In these embodiments, routing-policy language for a router includes two major constructs to a configuration, which may significantly reduce the amount of configuration required to specify routing policy. The first construct provides a basic modularity such that common blocks  
10   of policy may be specified once and reused. In some embodiments, hierarchical reuse may be used where a policy may reuse and/or make reference to one or more common policy blocks. More than one level of hierarchy may also be permitted. The second construct may allow common blocks of policy to be parameterized. Parameterization allows policies that share similar structure and  
15   may reference different values within that structure to be defined, stored and maintained once. Each variant or invocation of a parameterized policy may maintain appropriate parameters for a variant rather storing and maintaining a full copy of each variant of the policy.

          In some embodiments, a method and routing system may evaluate a  
20   configuration file to determine relationships between route attributes. The relationships may be expressed in one or more mathematical functions. When a route is received from a peer, the attributes of the route may be modified based on the mathematical functions.

          In some embodiments, a router and method for implementing routing  
25   policy using traffic engineering information are provided. In one embodiment, a method for implementing routing policy includes performing a translation of a policy configuration to generate an internal-policy representation. In the policy statement 'set med 10', *set* is the operator and *med* is the attribute. Attribute-operator pairings of the internal-policy representation may be verified with one  
30   or more client dynamic load libraries (DLLs). When the attribute-operator pairings are verified, the internal-policy representation may be compiled and

stored in a system database. A client protocol may be notified that the routing policy has been modified.

In some embodiments, routing policy may be implemented using sets and set operators. In these embodiments, a method of generating routing policy may  
5 comprise decoupling data items from actions associated with the data items, and building a routing policy by combining common components using set operations on the data items and the actions. In these embodiments, common data items that span across more than one domain may be reused for the more than one domain. In these embodiments, the data items may comprise prefixes,  
10 as-path expressions and community lists, for example. In these embodiments, the actions may comprise at least accept and deny actions. In these embodiments, a routing system may comprise a plurality of route or packet filters that share common data items for reuse across more than one domain. One or more processing elements may decouple data items from actions associated with the  
15 data items and may build a routing policy by combining common components using set operations on the data items and the actions.

In some embodiments, customers may control how policy statement operation are applied to in a policy. In these embodiments, a method of generating routing policy is provided which may comprise prefixing statements  
20 of a single routing policy with either source or sink designations. The method may also comprise applying statements with the source designations to match operations, and applying statements with the sink designations to set operations. In these embodiments, a routing system is also provided which may comprise a single routing policy comprising statements prefixed with either source or sink  
25 designations, and processing elements to apply the statements with the source designations to match operations, and to apply the statements with the sink designations to set operations.

In some embodiments, routing policy diagnostics are provided with the addition of an extension to policy language to allow generic signaling using  
30 event triggers, which may be user defined. In these embodiments, event triggers may be applied to routes received by routing system.

### Brief Description of the Drawings

The appended claims are directed to some of the various embodiments of the present invention. However, the detailed description presents a more complete understanding of embodiments of the present invention when  
5 considered in connection with the figures, wherein like reference numbers refer to similar items throughout the figures and:

FIG. 1 illustrates policy parameterization in accordance with some embodiments of the present invention;

FIG. 2 illustrates the application of a parameterized policy in accordance  
10 with some embodiments of the present invention;

FIG. 3 is a functional block diagram of a policy repository system and router in accordance with some embodiments of the present invention;

FIG. 4 is a flow-chart of a parameterizing procedure in accordance with some embodiments of the present invention;

FIG. 5 is a flow chart of a parameterized-policy application procedure in  
15 accordance with some embodiments of the present invention;

FIG. 6 is a flow chart of a route-policy-generation procedure in accordance with some embodiments of the present invention;

FIG. 7 is a flow chart of a router-configuration procedure which applies  
20 mathematical operations to route attributes in accordance with some embodiments of the present invention;

FIG. 8 illustrates the use of traffic engineering in routing policy in accordance with some embodiments of the present invention;

FIG. 9 illustrates the use of event triggers in accordance with some  
25 embodiments of the present invention; and

FIG. 10 illustrates policy staging in accordance with some embodiments of the present invention.

### Detailed Description

The following description and the drawings illustrate specific  
30 embodiments of the invention sufficiently to enable those skilled in the art to practice them. Other embodiments may incorporate structural, logical, electrical,

process, and other changes. Examples merely typify possible variations.

Individual components and functions are optional unless explicitly required, and the sequence of operations may vary. Portions and features of some embodiments may be included in or substituted for those of others. The scope of  
5   embodiments of the invention encompasses the full ambit of the claims and all available equivalents of those claims.

FIG. 1 illustrates policy parameterization in accordance with some embodiments of the present invention. A customer configuration, such as customer configuration 102, may comprise one or more routing policies. Each  
10   routing policy may comprise one or more policy statements. Examples of policy statements for a particular customer may include setting a community tag attribute or a multi-exit discriminator (MED) attribute to a particular value. Parameterization 104 may be performed on the policy statements to generate parameterized policy 106. A parameterized policy may comprise one or more  
15   parameterized-policy statements. In some embodiments, a parameterized policy may also include some policy statements that have not been parameterized. Each parameterized-policy statement may have a set of parameters 108 associated with a particular policy statement and/or customer's configuration. The parameters may be stored in a parameter table, although the scope of the invention is not  
20   limited in this respect. Other ways of associating parameters with customer configurations may also be used.

In some embodiments, common blocks of policy statements may be identified and may be used across different customer configurations. These common blocks of policy statements may include parameterized-policy  
25   statements as well as policy statements that are not parameterized. Accordingly, common blocks may be reused within a routing policy, as well as across different policies.

FIG. 2 illustrates the application of a parameterized policy in accordance with some embodiments of the present invention. In some embodiments, a  
30   parameterized policy may be applied when a route, such as route 202, is received as part of a route-update message from another routing system. During policy

application 204, one of parameterized policies 206 may be called with one of the sets of parameters 208 based on the customer or customer class. Route decision 210 may comprise determining whether to accept the route, whether to modify attributes of the route, or whether to send the route or the modified route to peer  
5 routing systems. When the route is accepted or modified, the accepted or the modified route may be installed on the router. When the route is modified, an attribute of the route may be changed, a new attribute may be created, or an attribute may be deleted, for example.

In accordance with some embodiments of the present invention, a  
10 parameterized-policy statement may utilize one or more parameters, and a parameterized-routing policy may include parameterized-policy statements as well as non-parameterized-policy statements. More than one parameterized-routing policy may be generated and be operated concurrently for a customer configuration. Furthermore, parameterized-routing policies may be used across  
15 different customer configurations. In some embodiments, parameterized routing policies may be used within other parameterized-routing policies.

In accordance with some embodiments of the present invention, one or more common blocks of policy statements may be identified. The common blocks may be common to more than one routing policy. A commonized routing  
20 policy may be generated from the one or more common blocks, and the commonized routing policy may be reused by calling the commonized routing policy from within the more than one routing policy which uses the common blocks. The commonized routing policy may include both parameterized-policy statements as well as policy statements that are not parameterized. In some  
25 embodiments, parameters may be assigned to at least some of the policy statements of the common blocks to parameterize some policy statements in the common blocks. When generating a commonized routing policy, a call to the one or more common blocks may be placed in the routing policy.

Conventionally policy configurations may take many additional lines of  
30 configuration to affect a desired result. One problem with these conventional configurations is that the need to vary only one value in the many lines of

configuration means that a whole block of the additional lines is repeated in the configuration for a new customer policy. This makes for large amounts of configuration that must be maintained, stored, processed and understood by the device and the user. In accordance with the embodiments illustrated in FIGs 1 and 2, parameterization and hierarchy are applied to routing policy and routing-policy configuration. In these embodiments, routing policy language for a router may include two major constructs to a configuration, which may help significantly reduce the amount of configuration to specify routing policy. Hierarchy provides a basic modularity so that common blocks of policy may be specified once and reused. Parameterization allows for specialized reuse of these common blocks. Further savings may result because reused blocks of configuration that may share the same structure but may reference different values within that common structure may not necessarily need to be repeated.

Adding parameterization and hierarchy may allow a user to define a policy configuration once and may allow the creation of as many variants as desired by referencing a common block with the appropriate parameters allowing a user to define many functions.

The following is an example of applying parameterization and hierarchy to routing policy and routing-policy configuration. In a new policy language, a simple parameterized policy, called "param\_example", may be defined which uses a local-preference and a community tag as parameters. Three policies (e.g., example\_1, example\_2, and example\_3) may then be built off this parameterized policy as illustrated below.

```
25      prefix-set rfc-1918
          10.0.0.0/8 ge 8 le 32,
          192.168.0.0/16 ge 16 le 32,
          0.0.0.0
          end-set
30
      route-policy param_example ( $pref, $comm-tag)
```

```

    if (destination in RFC-1918) then
        drop
    else
        set origin igp
5       set community (10:20, 10:30, 10:$comm-tag)
        set local-preference $lpref
    endif
end-policy

10    route-policy example_1
        apply param_example (100,100)
        pass
    end-policy

15    route-policy example_2
        apply param_example (200,200)
        pass
    end-policy

20    route-policy example_3
        apply param_example (300,300)
        pass
    end-policy

25    If these same three policies were implemented using a conventional
    policy mapping approach (e.g., IOS route-maps), the configuration may be
    expressed as follows:

    ip prefix-list RFC-1918
30    10 deny 10.0.0.0/8 ge 8 le 32
    20 deny 192.168.0.0/16 ge 16 le 32
```

```
        30 deny 0.0.0.0
    exit

    route-map example_1 permit 10
5      match ip address prefix-list RFC-1918
    exit
    route-map example_1 permit 20
        set tag 40
        set origin igp
10      set local-preference 100
        set community 10:20 10:30 10:100
    exit

    route-map example_2 permit 10
15      match ip address prefix-list RFC-1918
    exit
    route-map example_2 permit 20
        set tag 40
        set origin igp
20      set local-preference 200
        set community 10:20 10:30 10:200
    exit

    route-map example_3 permit 10
25      match ip address prefix-list RFC-1918
    exit
    route-map example_3 permit 20
        set tag 40
        set origin igp
30      set local-preference 300
        set community 10:20 10:30 10:300
```

exit

Note that in the route-map example, the complete body of the policy is repeated for each example. The differences are the two lines that set the local  
5 preference and the community value, but all other lines are repeated. Consider the situation in which the user then desires to change the tag value to 560. It must be modified in all 3 locations in the route-map example. Extrapolating this to a scale of several hundred or thousand policies, this becomes a significant item to maintain, store and comprehend. In accordance with some embodiments of the  
10 present invention, the language needs to be changed only in a common parameterized policy (e.g., param\_example). Thus, the use of parameterized policies may significantly reduce the size of policies in these situations.

Accordingly, the time to process a configuration and the requirements both on and off box required to store a configuration may be significantly  
15 reduced. This modularization and reuse may further reduce the maintenance requirements for a customer because one copy of a common block of configuration, for example, may be used rather than several copies spread all over their configuration space. Furthermore, large reductions in configuration may allow a user to have a clearer understanding of what a router is configured  
20 to do. Network outages due to missing portions of repeated configuration when changes are made may be reduced. In addition, network outages due to an incorrect understanding of the configuration may be reduced as the intent of the configuration becomes clearer.

FIG. 3 is a functional block diagram representing the policy repository  
25 system and router in accordance with some embodiments of the present invention. Policy repository system 302 may be used for generating routing policy and may comprise policy translator 306 which may perform a translation of policy configuration 308 to generate an internal-policy representation. The internal-policy representation may be generated for one or more policy  
30 statements comprising policy configuration 308. In some embodiments, policy

translator 306 may perform a lexical analysis on a policy configuration to generate an internal-policy representation.

Policy repository system 302 may also comprise policy repository 310 which may verify attribute-operator pairings of the internal-policy representation with one or more client dynamic load libraries (DLLs) 312. Policy repository 310 may compile the internal-policy representation when the attribute-operator pairings are verified. Policy repository system 302 may also include system database 316 to store one or more complied internal-policy representations. Policy repository system 302 may also include policy coordinator or controller 314 which may notify a client protocol that a complied routing policy has been modified. In some embodiments, policy repository system 302 may also include I/O device 318 to receive the policy configuration, which may be in the form of one or more policy statements. I/O device 318 may receive the policy configuration entered by a user or operator in the form of one or more policy statements. In some embodiments, the policy statements may be in a grammatical form (e.g., having a specific grammar). Router or routing system 304 may apply the routing policy to a route received from client protocol 320, such as the border-gateway protocol (BGP).

Policy repository 310 may verify each of several attribute-operator pairings of the internal-policy representation with the client DLLs. The client DLLs may include verification routines for the attributes and associated operators to allow the policy repository to query each attribute-operator pairing and pass arguments present in the configuration to each statement in the policy. Policy repository 310, as part of compiling, may generate the compiled internal-policy representation in a policy transmission language (PXL), although the scope of the invention is not limited in this respect.

Although system 302 and device 304 are illustrated as having several separate functional elements, one or more of the functional elements may be combined and may be implemented by combinations of software-configured elements, such as processing elements including digital signal processors (DSPs), and/or other hardware elements. For example, processing elements may

comprise one or more microprocessors, DSPs, application specific integrated circuits (ASICs), and combinations of various hardware and logic circuitry for performing at least the functions described herein.

Unless specifically stated otherwise, terms such as processing,  
5 computing, calculating, determining, displaying, or the like, may refer to an action and/or process of one or more processing or computing systems or similar devices that may manipulate and transform data represented as physical (e.g., electronic) quantities within a processing system's registers and memory into other data similarly represented as physical quantities within the processing  
10 system's registers or memories, or other such information storage, transmission or display devices. Furthermore, as used herein, computing device includes one or more processing elements coupled with computer readable memory that may be volatile or non-volatile memory or a combination thereof.

FIG. 4 is a flow chart of a parameterizing procedure in accordance with  
15 some embodiments of the present invention. Procedure 400 may be performed by a processing system, such as system 302 (FIG. 3) although the scope of the invention is not limited in this respect. In operation 402, common blocks of policy statements may be identified in a routing-policy configuration. The routing-policy configuration may be for a particular customer or a particular  
20 customer's configuration. In some embodiments, a customer configuration may comprise more than one policy. In these embodiments, operation 402 may comprise identifying common blocks of policy statements in each of the various policies, as well as identifying common blocks of policy statements across the different policies of the customer configuration.

25 In operation 404, parameters may be assigned to common policy statements of the routing-policy configuration. In some embodiments, sets of parameters may be assigned to common blocks of policy statements.

In operation 406, the parameters may be stored in a parameter table associated with the parameterized policy and customer configuration.  
30 Accordingly, a parameterized policy may be called with parameters from the parameter table, and may be based on the customer configuration.

In operation 408, the parameterized policy may be generated by reusing the common blocks of policy with the assigned parameters. The reuse of common blocks of policy in a parameterized policy may significantly reduce the size of a customer configuration resulting in a much more manageable system, especially for very large configurations.

FIG. 5 is a flow chart of a parameterized policy application procedure in accordance with some embodiments of the present invention. Parameterized policy application procedure 500 may be performed by a system, such as system 302 (FIG. 3) although other systems may also perform procedure 500. In some embodiments, a parameterized policy may include both parameterized and non-parameterized policy statements.

In operation 502, a route may be received from a peer system. The route may be received as part of a route-update message, although this is not a requirement.

In operation 504, a policy associated with the route may be identified. The policy may be a parameterized policy or a non-parameterized policy. In some embodiments, the associated policy may be identified from information in the route. When the identified policy is a parameterized policy, operation 506 and 508 may be performed. In operation 506, the parameters for the identified policy may be looked up (e.g., in a parameter table) depending on, for example, the customer or customer class.

In operation 508, the policy may be called with the parameters from the table, and in operation 510, the policy may be applied to the received route. Operation 510 may include accepting, rejecting or modifying the route, as well as saving the accepted or modified route.

FIG. 6 is a flow chart of a route policy generation procedure in accordance with some embodiments of the present invention. Procedure 600 may be performed by a system, such as system 302 (FIG. 3) although other systems may also be suitable. In embodiments, procedure 600 may be performed on a continual or substantially continual basis to generate and apply policy to routes.

In operation 602, a policy configuration is received in the form of one or more policy statements. In some embodiments, the policy configuration may be entered by a user or operator in the form of one or more policy statements. In some embodiments, the policy statements may be in grammatical form. In some  
5 embodiments, a lexical analysis may be performed on a policy configuration to generate an internal-policy representation.

In operation 604, a policy translation may be performed on the policy configuration to generate an internal-policy representation. The internal-policy representation may provide pairings between attributes and operators and the  
10 arguments associated with those pairings. In some embodiments, a route-policy configuration may be defined by lexical, grammatical and semantic rules, which may be used to build the internal representation that provides the pairings between attributes and operators.

In operation 606, attribute-operator pairings of the internal-policy  
15 representation may be verified with one or more client dynamic load libraries (DLLs). In some embodiments, operation 606 may include verifying each of a plurality of attribute-operator pairings of the internal-policy representation with the client DLLs. The client DLLs may include verification routines for the attributes and associated operators to allow a policy repository to query each  
20 attribute-operator pairing and may pass arguments present in the configuration to each statement in the policy.

Operation 608 determines whether or not the attribute-operator pairings have been verified. When any one of the pairings cannot be verified, the policy configuration may be invalid and a system administrator or user may be notified  
25 in operation 610. Procedure 600 may be performed for other policy configurations. When operation 608 determines that all the pairings can be verified, operation 612 may be performed.

In operation 612, the internal-policy representation may be stored to allow interrogation by the user. In operation 614, the internal-policy  
30 representation is compiled. In operation 616, the complied policy representation is stored in a system database. In some embodiments, the compiled internal-

policy representation may be generated and stored in a policy transmission language (PXL).

5 In operation 618, a client protocol, such as BGP, is notified that the routing policy has changed so that the protocol can take appropriate measures when the policy is in use. When the policy is just being created, the new policy may now be available for use by the protocol.

In operation 620, portions of procedure 600 may be repeated for other policy configurations. Operation 620 is an optional operation and nothing requires it be performed in the sequence illustrated.

10 In operation 622, the routing policy may be applied to a route received from the client protocol (e.g., as part of a BGP route-update message). In some embodiments, a RIB entry may also be updated.

Although the individual operations of procedure 600 are illustrated and described as separate operations, one or more of the individual operations may  
15 be performed concurrently and nothing requires that the operations be performed in the order illustrated.

FIG. 7 is a flow chart of a router-configuration procedure which applies mathematical operations to route attributes in accordance with some  
20 embodiments of the present invention. Procedure 700 may be performed by a routing system, and some embodiments, may be performed by system 302 (FIG. 3), although other systems may also be suitable. Conventional approaches to assigning route attributes generally use simple match and assign operations. Often these are used to express relationships between different values. For  
25 example a local-preference may be assigned based on a MED value or a community tag value. Direct mappings between these attribute spaces are quite commonly used by service providers. One problem with conventional approaches to assigning route attributes is that there may be no or limited ability to express the relationships between different route values, and thus, the user may be forced to enumerate all the possible cases in a configuration.

30 In accordance with some embodiments of the present invention, mathematical operations are applied to routing policy. In operation 702, a

configuration file may be evaluated to determine relationships between route attributes. Operation 704 may generate one or more mathematical functions based on the relationships between route attributes determined in operation 702. Operation 704 may further consider customer policy 706 in generating the  
5 mathematical functions. In some embodiments, customer policy 706 may be a parameterized policy as discussed above.

In operation 708, the configuration file may be updated, revised and saved, although this is not a requirement. When a route is received (e.g., from a peer), operation 710 may comprise modifying one or more of the attributes of the  
10 received route based on the mathematical functions generated in operation 706.

In some embodiments, operation 708 may comprise generating a revised configuration file which expresses the relationships between the route attributes with the one or more mathematical functions, and operation 710 may comprise modifying the attributes of the received route using the revised configuration file.

15 In some embodiments, a received packet may be routed using the received route with the modified attributes. In some embodiments, the one or more mathematical functions comprises at least one of: adding an offset to a value of a first attribute for a determined value of a second attribute; and multiplying the value of the first attribute by a factor for the determined value of  
20 the second attribute. The first and second attributes can comprise, but are not limited to, a community tag attribute, a local preference attribute, and/or a multi-exit discriminator (MED) attribute. They may also comprise any other route attribute or portion of a route attribute.

In some embodiments, the values of variable transformations in operation  
25 704 may be expressed as one or more logical mathematical functions. For example, the local-preference attribute may be set to the lower 16 bits of a community tag + 10 or to the value of the MED attribute. In these embodiments, the capabilities to retrieve these attribute values and build mathematical expressions using these values allows a user or operator to set the values of other  
30 attributes. For example, a percent sign may be used to indicate that the value of a retrieved route attribute is being operated on.

An example of building expressions follows:

```
set community 1234: (%med + 10)
```

This may set the lower 16 bits of the community to the value of the med in the route if any + 10.

5        In another example:

```
if (community in allowed_communities) then
```

```
    set local-preference %matched_community & 0x0000ffff + 10
```

```
endif
```

10        This may set the local-preference to "the lower 16 bits of the matched community value + 10" for any routes that had communities in the list of allowed communities.

Setting attribute values using mathematical expressions may allow a greater range of values to be used without having to enumerate all the possible cases in the configuration. This permits a finer granularity of attribute manipulation without having to increase configuration storage space. In addition, when a translation of attribute values is desired, having the translation expression present in the configuration makes this fact much more obvious to the user. The mapping information about how to set local-preferences or community values, for example, may be referenced directly in the configuration rather than having to refer to separately maintained documentation. This may make the intent of policy clearer to the user attempting to understand it.

FIG. 8 illustrates the use of incorporating traffic engineering information in routing policy in accordance with some embodiments of the present invention. In these embodiments, an operator or user may incorporate additional information, such as traffic statistics, when altering route attributes. One problem with conventional routing systems is that conventional systems may not allow direct access to information outside of the route attributes proper. In accordance with these embodiments, routing system 802 may route traffic 804 based on routing information, which may be stored in a database such as routing information base (RIB) 806. RIB 806 may have been generated from the application of routing policy 808 in accordance with many techniques, including

those previously discussed. Traffic evaluator 810 may evaluate traffic 804 to generate information, such as traffic statistics, for particular routes. This information may be stored in traffic database 811. This information may be used to by routing policy 808 to alter route attributes for eventual inclusion in RIB

5 806. These embodiments of the present invention provide direct access to information outside of the route attributes proper. In accordance with these embodiments, the architecture of a policy infrastructure may be sufficiently extensible to allow traffic information to be considered when performing routing policy transformations. Route attributes may be set and/or modified based on

10 traffic engineering information generated from routing system 802.

For example, traffic evaluator 810 may learn that some routes utilize a congested link, and may tag these routes or may have their preferences set so that the congested links are used when alternatives links are not available. In these embodiments, any characteristic which may be measured and compared against

15 by traffic evaluator 810 may be used to alter route attributes. For example, such characteristics may include static characteristics such as the bandwidth of a link, or more dynamic characteristics such as the number of dropped or discarded packets on an interface, as well as the available bandwidth on an interface. In some cases, the state of protocols may be checked and/or changed based on this

20 information.

FIG. 9 illustrates the use of event triggers in accordance with some embodiments of the present invention. In these embodiments, routing policy diagnostics are provided with the addition of an extension to policy language to allow generic signaling using event triggers, which may be user defined. In these

25 embodiments, event triggers 902 may be applied to routes 903 received by routing system 904. The application of event triggers 902 may result in a triggered event which may result in one or more actions 906. Actions 906 may include, for example, logging the event, modifying a route attribute based on the event, taking down a peer from which the route was received, and/or changing

30 the system configuration based on the triggered event. In some embodiments, actions 906 may include actions not directly related to a route or route attribute.

In some embodiments, routing-protocol diagnostics are provided for routing policy 908. These embodiments allow for a greater understanding of the router and network state, and may provide mechanisms which allow for trapping and responding to errors when under stress as well as for dealing with abnormal events. In one example, the number of routes received from a specific peer may be limited. In another example, specific blocks of address space on a peer may be filtered. These embodiments may allow other events in the network to be able to be tracked by event triggers 902.

In these embodiments, an extension to the policy language may be added that allows the user to define triggers in a general manner. This may be used anywhere in the policy where any action may be taken. These triggers may be then turned into various types of events such as system-log messages, as well as any other events that the user may monitor remotely using conventional mechanisms. Event triggers 902 may also be used to affect changes in application state. For example, actions 906 may comprise actions such as sending a notification message, taking a peer down, modifying dampening parameters or changing a max-prefix limit, for example.

These embodiments may help users detect events on networks, and may allow users to create events that they wish to monitor. For example, there is often boilerplate policy that is put into place to protect the network, such as filtering of RFC-1918 address space or default routes. In addition to the normal drop, modify, and accept notions of policy, any or all of these protection mechanisms may be used by event triggers 902 to create events that may be monitored. In some embodiments, this may occur directly as a policy executes and may allow for earlier detection of some class of "abnormal" events.

In some embodiments, event triggers 902 may be used to identify and track protocol specific events. For example, a BGP notice may be sent to bring down a peer that is misbehaving, or the dampening parameters on a peer that is flapping routes may be aggressively increased. In some embodiments, event triggers 902 may be 'a part of' or may be 'checked' by routing policy 908.

FIG. 10 illustrates policy staging in accordance with some embodiments of the present invention. In accordance with these embodiments, policy staging may allow a comparison between policies at a single attach point, and may be performed before a policy is implemented. Conventionally, it has not been possible to determine the effects that a new policy may have on a route or set of routes in a network until after the policy has actually been applied. The statements in a policy may have a profound effect not just on routers within a network, but may also have profound effects on external networks. The application of routing policy controls the distribution and acceptance of routes between routing protocols and between neighboring routers.

In these embodiments, policy staging may also provide the ability to tell that the policies are different and where they are different. In these embodiments, policy staging may also tell what the result for a particular prefix would be for both policies. For example, policy staging element 1000 may apply two or more policies from routing policies 1002 to a received route 1004. Routing policies 1002 may include existing routing policies as well as staged-routing policies. Results 1006 may be provided for each of the policies. In these embodiments, policy staging element 1000 may also pass results 1006 of a staged policy to routing information base (RIB) 1008, and may determine how the results would change the RIB. The routes may be specially marked so as to not influence the current routing information allowing a user the ability to do a comparison, or to determine how the forwarding table of RIB 1008 would change with the application of the new (e.g., staged) policy.

Accordingly, policies may be tested and evaluated for different scenarios before they are applied to an attach point. In this way, the user may know before hand exactly what impact a new policy will have on a peer, and how it will affect the RIB and thus forwarding. This ability may help prevent network outages by preventing a disruptive change from being applied in the first place.

In some embodiments, policies, such as “my policy” and “stage-1”, may be compared by prepending a value in the as-path for matched routes of one policy, and prepending another value in the as-path for matched routes of the

other policy. An operation may be defined to identify to a user that the policies are different and neither is dropped. Routes that have been updated and/or dropped with policy "stage-1" may be specifically marked so that these changes do not affect the current running system, but yet are stored in the RIB.

- 5 Accordingly, what is currently in the RIB may be compared by applying policy "stage-1".

In accordance with some embodiments of the present invention, set operations may be performed on source route information, and match operations may be performed on sink or result information as it is being constructed. In  
10 these embodiments, both of these approaches may be combined in one policy. Accordingly, customers and/or users may control the application of policy statements to routing policy and routing-policy configuration.

In these embodiments, the current capabilities of the routing policy language may be enhanced to give the network engineer the ability to specify, for  
15 each statement in a policy, that the statement should perform its operation on source or sink data. The user may prefix each operation with one of the following designations: "source" or "sink". By default, the "source" designation may be applied to match operations, and the "sink" designation may be applied to set operations to follow the approach that currently dominates the market  
20 place and to reduce the complexity of the configuration. Consider the following example which sets the MED for destinations in the set "FOO" and then later does a comparison on the MED value that may or may not have been previously altered.

```
route-policy test_med
25   if (destination in FOO) then
       set med igp-cost
   endif
   ....
   if (sink.med gt 20000) then
30     drop
   endif
```

end-policy

These embodiments may help expand the scope and capabilities of the current approaches of applying policy to routing, and thus may offer network engineers the ability to write policies that were never before possible.

5 Furthermore, this embodiment may allow for new flexibility in the policies that users write. In these embodiments, concepts such as "if this policy has not already prepended an as-path then take actions x y and z" may be expressed, for example. By providing this new functionality, network engineers may be able to tune their networks in ways never before possible.

10 In some embodiments, routing policy may use sets to decouple data from actions allowing the reuse of data. Conventional configuration of routing policy uses data containers that associate groups of data directly with actions. The actions may be directly coupled with the data. Conventionally, this is done with a list of data such as prefixes, as-path regular expressions, community-lists etc and  
15 an entry signifying a notion of accept or deny. In conventional systems, directly coupling this data with accept and deny actions presents several problems. For example, data that may be common to more than one domain generally may not be reused across the domains. Consider the case of packet filtering and route  
20 filtering by prefix. The prefix data may overlap in both the route filters and the packet filters, but because actions are directly associated with the data and packet filtering usually requires looking at additional fields of data (e.g., src port) in the packet that are not present in the route updates and vice versa, any common prefix data may not be shared across the two domains. For example in an IOS configuration, a route-filter that may look like this:

25 ip prefix-list example  
10 deny 10.0.0.0/8 ge 8 le 32  
20 deny 192.168.0.0/16 ge 16 le 32  
30 permit 222.222.222.0/24  
40 permit 222.222.111.0/24  
50 permit 222.111.222.0/24  
60 permit 222.111.111.0/24

```

70 permit 222.110.222.0/24
80 permit 222.110.111.0/24
90 permit 222.101.222.0/24
100 permit 222.101.111.0/24

```

5

A packet filter may look like this:

```
ip access-list extended example_extended
```

```
10 deny ip any 10.0.0.0 255.0.0.0
```

```
20 deny ip any 192.168.0.0 255.255.0.0
```

```
10 30 permit tcp any 222.222.222.0/24 established
```

```
40 permit tcp any 222.222.111.0/24 established
```

```
50 permit tcp any 222.111.222.0/24 established
```

```
60 permit tcp any 222.111.111.0/24 established
```

```
70 permit tcp any 222.110.222.0/24 established
```

```
15 80 permit tcp any 222.110.111.0/24 established
```

```
90 permit tcp any 222.101.222.0/24 established
```

```
100 permit tcp any 222.101.111.0/24 established
```

Note that identical prefix data for all of the lines is repeated in both the packet and the route filter. Since the configuration specification requires the associated actions and different fields be specified in the list, the common prefix data is repeated in each list. Associating actions directly with the data makes combining this data together difficult. When a user or operator may wish to negate the result of a comparison and combine it with another, it becomes semantically difficult to understand the intent. A user or operator might wish to define a policy which says, "If route X is in list A, but not in list B then set the local-preference to 100". However this may be difficult to do as the semantics of negating the match of an ACL, which contains both permit and deny statements may not be clear. Hence coupling the actions directly with the data may tend to force a user or operator to use single long lists rather than allowing the user or operator to combine together common components.

In accordance with embodiments of the present invention, the notion of sets and independent operations on sets of data in configuring policy are used. A set may be a collection of data elements. In these embodiments, the notion of acceptance or denial directly is decoupled from the data. This decoupling of the data containers from actions on the data allows policies to be constructed in many more unique ways than conventional mechanisms provide. Finally, the introduction of sets allows data to be combined together using conventional set operations like union and intersection etc.

Embodiments of the present invention which decouple the data from actions have several advantages. First, since actions are decoupled, data that span different domains may be reused without having to maintain multiple copies of the configuration data. Thus when defining route and packet filters that share the same prefix data, the prefix data may be specified once and reused across the two domains. This may lead to more efficient configuration and less maintenance of that data for the user. Secondly, building complex comparisons becomes semantically tractable. For example, on a peering router, a user or operator may wish to have a policy that says only accept a specific set of routes from peer A and never send them to peer B. If this is done with conventional prefix-based mechanisms, then two lists must be maintained. One list is the inverse of the other. By decoupling the actions and storing the prefixes as a set, this becomes much simpler. The set may be defined once and Boolean tests for membership in the set may be used to affect the policies for peers A and B. These tests of set membership may be combined together using Boolean operators “and”, “or” and “not”, to build more advanced comparisons. Consider defining a policy which explicitly drops all routes in a particular address space, all routes that are very specific such as /32 host routes, and any routes from network blocks that one owns. Finally, accept any routes that are expected from autonomous system (AS) number 1234. This might be a typical filter a user or operator may wish to install on a peering connection with AS 1234. Building a Boolean expression on various sets, the user may express that policy as follows:

if (((destination in RFC-1918) or

```

        (destination in my_prefixes) or
        (destination in too_specific))
        and (not destination in allowed_routes_from_as_1234)) then
            drop
5         else
            set local-preference 100
        endif

```

Writing a policy in this manner makes the intent of the policy much  
 10 clearer than in conventional systems. Providing Boolean operators to combine  
 the corresponding lists that currently exist in many configuration languages  
 becomes intractable very quickly because of the embedding of the actions of  
 permit and deny within the list structures themselves. Using Boolean operators to  
 combine operations allows the user to be explicit, while still having mechanisms  
 15 that are understandable and scalable. Finally, since these sets are simply  
 collections of common data, it would also become possible to build together  
 larger sets out of a smaller set by using set union and intersection operators. This  
 may also reduce configuration requirements.

Embodiments of the invention may be implemented in one or a  
 20 combination of hardware, firmware and software. Embodiments of the invention  
 may also be implemented as instructions stored on a machine-readable medium,  
 which may be read and executed by at least one processor to perform the  
 operations described herein. A machine-readable medium may include any  
 mechanism for storing or transmitting information in a form readable by a  
 25 machine (e.g., a computer). For example, a machine-readable medium may  
 include read-only memory (ROM), random-access memory (RAM), magnetic  
 disk storage media, optical storage media, flash-memory devices, electrical,  
 optical, acoustical or other form of propagated signals (e.g., carrier waver,  
 infrared signals, digital signals, etc.), and others.

30 It is emphasized that the Abstract is provided to comply with 37 C.F.R.  
 Section 1.72(b) requiring an abstract that will allow the reader to ascertain the

nature and gist of the technical disclosure. It is submitted with the understanding that it will not be used to limit or interpret the scope or meaning of the claims.

In the foregoing detailed description, various features are occasionally grouped together in a single embodiment for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments of the subject matter require more features that are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the detailed description, with each claim standing on its own as a separate preferred embodiment.

## CLAIMS

What is claimed is:

5

1. A method comprising:  
parameterizing a routing policy; and  
applying the parameterized-routing policy to a route.

10

2. The method of claim 1 wherein the routing policy comprises a plurality of policy statements, and wherein parameterizing comprises assigning parameters to at least some of the policy statements and refraining from assigning parameters to at least some other of the policy statements to generate the parameterized-routing policy.

15

3. The method of claim 1 wherein parameterizing comprises:  
for the routing policy, generating at least one parameterized-policy statement having an associated set of parameters for one of either a customer or customer class.

20

4. The method of claim 1 wherein the routing policy comprises a plurality of policy statements, each policy statement having one or more differing values associated with one or more customers or customer classes, and wherein parameterizing comprises assigning parameters to the one or more differing values of the policy statements.

25

5. The method of claim 1 wherein parameterizing further comprises:  
identifying one or more common blocks of policy statements within the policy;  
assigning sets of parameters to elements of the one or more common blocks; and

storing the parameter sets in a parameter table, the table associating each set of parameters with either the customer or the customer class.

6. The method of claim 5 wherein parameterizing further comprises reusing the common blocks in the parameterized-routing policy.

5           7. The method of claim 6 wherein parameterizing further comprises reusing the common blocks in another parameterized-routing policy.

8. The method of claim 6 wherein reusing the common blocks comprises calling a parameterized policy with parameters from the parameter table based on one of either the customer or the customer class.

10           9. The method of claim 5 wherein applying further comprises determining at least one of whether to accept the route, whether to modify attributes of the route, or whether to send the route or the modified route to peer routing systems.

15           10. The method of claim 9 wherein when the route is accepted or modified, applying further comprises installing the accepted or the modified route.

11. The method of claim 9 further comprising modifying attributes of the route, wherein modifying comprises at least one of changing an attribute, creating a new attribute, or deleting an attribute of the route.

20           12. The method of claim 1 further comprising:  
            identifying one or more common blocks of policy statements, the common blocks being common to more than one routing policy;  
            generating a commonized routing policy from the one or more common blocks; and

reusing the commonized routing policy by calling the commonized routing policy from within the more than one routing policy which uses the common blocks.

13. The method of claim 12 wherein parameterizing comprises assigning  
5 parameters to at least some of the policy statements of the common blocks to parameterize at least some policy statements in the common blocks.

14. A routing apparatus comprising:  
a processor to parameterize a routing policy and apply the parameterized-  
routing policy to a received route; and  
10 a storage element to store parameters associated with the parameterized-  
routing policy.

15. The apparatus of claim 14 wherein the routing policy comprises a plurality of policy statements, and wherein the processor is to assign parameters to at least some of the policy statements and is to refrain from assigning  
15 parameters to at least some other of the policy statements to generate the parameterized-routing policy,  
and wherein the processor is to store the assigned parameters in the storage element.

16. The apparatus of claim 14 wherein the processor is to generate at  
20 least one parameterized-policy statement having an associated set of parameters for one of either a customer or customer class.

17. The apparatus of claim 14 wherein the routing policy comprises a plurality of policy statements, each policy statement having one or more differing values associated with one or more customers or customer classes, and  
25 wherein the processor is to assign parameters to the one or more differing values of the policy statements.

18. The apparatus of claim 14 wherein the processor is to

identify one or more common blocks of policy statements within the policy;

assign sets of parameters to elements of the one or more common blocks;

and

5           store the parameter sets in a parameter table of the storage element, the table associating each set of parameters with either the customer or the customer class.

19. The apparatus of claim 18 wherein the processor is to reuse the common blocks in the parameterized-routing policy.

10           20. The apparatus of claim 19 wherein the processor is to reuse the common blocks in another parameterized-routing policy.

21. The apparatus of claim 19 wherein the processor, as part of reusing, is to call a parameterized policy with parameters from the parameter table based on one of either the customer or the customer class.

15           22. The apparatus of claim 18 wherein the processor is to determine at least one of whether to accept the route, whether to modify attributes of the route, or whether to send the route or the modified route to peer routing systems.

23. The apparatus of claim 22 wherein when the route is accepted or modified, the processor is to install the accepted or the modified route on a  
20   router.

24. The apparatus of claim 22 wherein the processor is to modify attributes of the route by at least one of changing an attribute, creating a new attribute, or deleting an attribute of the route.

25           25. The apparatus of claim 14 wherein the processor is to further:  
25           identify one or more common blocks of policy statements, the common blocks being common to more than one routing policy;

generate a commonized routing policy from the one or more common blocks; and

reuse the commonized routing policy by calling the commonized routing policy from within the more than one routing policy which uses the common  
5 blocks.

26. The apparatus of claim 25 wherein the processor is to assign parameters to at least some of the policy statements of the common blocks to parameterize the at least some policy statements in the common blocks.

27. A system comprising:  
10 means for parameterizing a routing policy;  
means for applying the parameterized-routing policy to a received route;  
and  
means for storing parameters associated with the parameterized-routing policy.

15 28. The system of claim 27 wherein the routing policy comprises a plurality of policy statements, and wherein the means for parameterizing is to assign parameters to at least some of the policy statements and is to refrain from assigning parameters to at least some other of the policy statements to generate the parameterized-routing policy,  
20 and wherein the means for parameterizing is to store the assigned parameters in the means for storing.

29. The system of claim 27 wherein the means for parameterizing is to generate at least one parameterized-policy statement having an associated set of parameters for one of either a customer or customer class.

25 30. The system of claim 27 wherein the routing policy comprises a plurality of policy statements, each policy statement having one or more differing values associated with one or more customers or customer classes, and

wherein the means for parameterizing is to assign parameters to the one or more differing values of the policy statements.

31. The system of claim 27 wherein the means for parameterizing is to further:

- 5           identify one or more common blocks of policy statements within the policy;  
            assign sets of parameters to elements of the one or more common blocks;  
            and  
            store the parameter sets in a parameter table of the storage element, the  
10     table associating each set of parameters with either the customer or the customer class.

32. The system of claim 31 wherein the means for applying is to reuse the common blocks in the parameterized-routing policy.

33. The system of claim 32 wherein the means for applying is to reuse the  
15     common blocks in another parameterized-routing policy.

34. The system of claim 32 wherein the means for applying, as part of reusing, is to call a parameterized policy with parameters from the parameter table based on one of either the customer or the customer class.

35. The system of claim 31 wherein the means for applying is to  
20     determine at least one of whether to accept the route, whether to modify attributes of the route, or whether to send the route or the modified route to peer routing systems.

36. The system of claim 35 wherein when the route is accepted or modified, the means for applying is to install the accepted or the modified route  
25     on a router.

37. The system of claim 35 wherein the means for applying is to modify attributes of the route by at least one of changing an attribute, creating a new attribute, or deleting an attribute of the route.

5           38. The system of claim 27 wherein the means for parameterizing is to:  
identify one or more common blocks of policy statements, the common  
blocks being common to more than one routing policy; and  
generate a commonized routing policy from the one or more common  
blocks, and  
10           wherein the means for applying is to reuse the commonized routing  
policy by calling the commonized routing policy from within the more than one  
routing policy which uses the common blocks.

39. The system of claim 38 wherein the means for parameterizing is to assign parameters to at least some of the policy statements of the common blocks to parameterize the at least some policy statements in the common blocks.

15           40. A machine-readable medium that provides instructions, which when  
executed by one or more processors, cause said processors to perform operations  
comprising:  
parameterizing a routing policy; and  
applying the parameterized-routing policy to a route.

20           41. The machine-readable medium of claim 40 wherein the instructions,  
when further executed by one or more of said processors cause said processors to  
perform operations, wherein the routing policy comprises a plurality of policy  
statements, and wherein parameterizing comprises assigning parameters to at  
least some of the policy statements and refraining from assigning parameters to  
25           at least some other of the policy statements to generate the parameterized-routing  
policy.

42. The machine-readable medium of claim 40 wherein the instructions,  
when further executed by one or more of said processors cause said processors to

perform operations, wherein parameterizing comprises: for the routing policy, generating at least one parameterized-policy statement having an associated set of parameters for one of either a customer or customer class.

43. The machine-readable medium of claim 40 wherein the instructions,  
5 when further executed by one or more of said processors cause said processors to perform operations wherein the routing policy comprises a plurality of policy statements, each policy statement having one or more differing values associated with one or more customers or customer classes.

44. The machine-readable medium of claim 43 wherein the instructions,  
10 when further executed by one or more of said processors cause said processors to perform operations wherein parameterizing comprises assigning parameters to the one or more differing values of the policy statements.

45. The machine-readable medium of claim 40 wherein the instructions,  
when further executed by one or more of said processors cause said processors to  
15 perform operations comprising:  
    identifying one or more common blocks of policy statements within the policy;  
    assigning sets of parameters to elements of the one or more common blocks; and  
20 storing the parameter sets in a parameter table, the table associating each set of parameters with either the customer or the customer class.

46. The machine-readable medium of claim 45 wherein the instructions,  
when further executed by one or more of said processors cause said processors to perform operations comprising reusing the common blocks in the parameterized-  
25 routing policy.

47. The machine-readable medium of claim 45 wherein the instructions,  
when further executed by one or more of said processors cause said processors to

perform operations comprising reusing the common blocks in another parameterized-routing policy.

48. The machine-readable medium of claim 46 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations comprising reusing the common blocks comprises calling a parameterized policy with parameters from the parameter table based on one of either the customer or the customer class.

49. The machine-readable medium of claim 45 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations comprising applying further comprises determining at least one of whether to accept the route, whether to modify attributes of the route, or whether to send the route or the modified route to peer routing systems.

50. The machine-readable medium of claim 40 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations further comprising:

identifying one or more common blocks of policy statements, the common blocks being common to more than one routing policy;  
generating a commonized routing policy from the one or more common blocks; and

reusing the commonized routing policy by calling the commonized routing policy from within the more than one routing policy which uses the common blocks.

51. A method for implementing routing policy comprising:  
performing a policy translation on a policy configuration to generate an internal-policy representation;  
verifying attribute-operator pairings of the internal-policy representation with one or more client dynamic load libraries (DLLs); and

when the attribute-operator pairings have been verified, compiling the internal-policy representation and storing the compiled internal-policy representation in a system database.

52. The method as claimed in claim 51 further comprising notifying a client protocol that the routing policy has been modified.

53. The method as claimed in claim 52 further comprising, after notifying, applying the new policy to a route received from the client protocol.

54. The method as claimed in claim 51 further comprising receiving the policy configuration in the form of one or more policy statements.

55. The method as claimed in claim 51 further comprising receiving the policy configuration entered by a user or system administrator in the form of one or more policy statements, the policy statements being in grammatical form.

56. The method as claimed in claim 51 wherein verifying comprises verifying each of a plurality of attribute-operator pairings of the internal-policy representation with the client DLLs.

57. The method as claimed in claim 56 wherein the client DLLs include verification routines for the attributes and associated operators to allow a policy repository to query each attribute-operator pairing and to verify arguments present in the configuration for each statement in the policy.

58. The method as claimed in claim 51 wherein compiling further comprises generating the compiled internal-policy representation in a policy transmission language (PXL).

59. The method as claimed in claim 51 further comprising parameterizing the routing policy.

60. A system for generating routing policy comprising:  
a translator to perform a policy translation on a policy configuration to generate an internal-policy representation; and  
a policy repository to verify attribute-operator pairings of the internal-policy representation with one or more client dynamic load libraries (DLLs), the  
5 policy repository to compile the internal-policy representation when the attribute-operator pairings are verified.

61. The system of claim 60 wherein the policy repository is to verify arguments of the attribute-operator pairings.

10 62. The system as claimed in claim 60 further comprising a router to apply the new policy to a route received from the client protocol.

63. The system as claimed in claim 60 further comprising an I/O device to receive the policy configuration in the form of one or more policy statements.

15 64. The system as claimed in claim 60 further comprising an I/O device to receive the policy configuration entered by a system administrator or user in the form of one or more policy statements, the policy statements being in a grammatical form.

20 65. The system as claimed in claim 60 wherein the policy repository is to verify each of a plurality of attribute-operator pairings of the internal-policy representation with the client DLLs, and is to further verify arguments of the pairings with the client DLLs.

25 66. The system of claim 65 wherein the client DLLs comprise verification routines for the attributes and associated operators to allow the policy repository to query each attribute-operator pairing and to verify arguments present in the configuration with each statement in the policy.

67. The system as claimed in claim 60 wherein the policy repository, as part of compiling, is to generate the compiled internal-policy representation in a policy transmission language (PXL).

68. The system as claimed in claim 60 further comprising a system  
5 database to store the complied internal-policy representation.

69. A machine-readable medium that provides instructions, which when executed by one or more processors, cause said processors to perform operations comprising:

performing a policy translation on a policy configuration to generate an  
10 internal-policy representation;

verifying attribute-operator pairings of the internal-policy representation with one or more client dynamic load libraries (DLLs); and

when the attribute-operator pairings are verified, compiling the internal-policy representation and storing the complied internal-policy representation in a  
15 system database.

70. The machine-readable medium of claim 69 wherein the instructions, when further executed by the said processors result in:

receiving the policy configuration entered by a user or system administrator in the form of one or more policy statements, the policy statements  
20 being in grammatical form;

notifying a client protocol that the routing policy has been modified; and  
applying the new policy to a route received from the client protocol

71. The machine-readable medium of claim 70 wherein the instructions, when further executed by said processors result in:

25 verifying each of a plurality of attribute-operator pairings of the internal-policy representation with the client DLLs, wherein the client DLLs include verification routines for the attributes and associated operators to allow a policy repository to query each attribute-operator pairing and to verify arguments present in the configuration to each statement in the policy; and

generating the compiled internal-policy representation in a policy transmission language (PXL).

72. A system for generating routing policy comprising:
- means for performing a policy translation on a policy configuration to
- 5 generate an internal-policy representation;
- means for verifying attribute-operator pairings of the internal-policy representation with one or more client dynamic load libraries (DLLs);
- means for compiling the internal-policy representation when the attribute-operator pairings verify; and
- 10 means for notifying a client protocol that the routing policy has been modified.

73. The system of claim 72 further comprising means for verifying arguments of the attribute-operator pairings;

74. The system of claim 72 further comprising means for applying the
- 15 new policy to a route received from the client protocol.

75. The system of claim 72 further comprising means for altering application state.

76. The system of claim 72 further comprising means for logging events.

77. The system of claim 72 further comprising means for altering
- 20 configuration values.

78. A method of altering route attributes in a running network comprising:
- measuring characteristics available to the system, the characteristics including route and non-route related characteristics; and
- 25 modifying route attributes of an existing route based on the measured characteristic.

79. The method of claim 78 further comprising tagging the existing route when a characteristic exceeds a predetermined measurement amount, and wherein modifying comprises dynamically modifying the route attributes based on the tagging.

5           80. The method of claim 79, wherein the characteristic includes a traffic statistic including at least one of either bandwidth or a number of dropped packets of a link.

81. A routing system comprising:  
a traffic evaluator to measure characteristics available to the system, the  
10 characteristics including route and non-route related characteristics; and  
a processing element to modify route attributes of an existing route based on the measured characteristic.

82. The routing system of claim 81 wherein the traffic evaluator is to tag the existing route when a characteristic exceeds a predetermined measurement  
15 amount, and  
wherein the processing element is to dynamically modify the route attributes based on the tagging.

83. The routing system of claim 82, wherein the characteristic includes a traffic statistic including at least one of either bandwidth or a number of dropped  
20 packets of a link.

84. A routing system comprising:  
means for measuring characteristics available to the system, the  
characteristics including route and non-route related characteristics; and  
means for modifying route attributes of an existing route based on the  
25 measured characteristic.

85. The system of claim 84 further comprising means for tagging the existing route when a characteristic exceeds a predetermined measurement amount, and

5 wherein the means for modifying comprises means for dynamically modifying the route attributes based on the tagging.

86. The method of claim 84, wherein the characteristic includes a traffic statistic including at least one of either bandwidth or a number of dropped packets of a link.

87. A machine-readable medium that provides instructions, which when  
10 executed by one or more processors, cause said processors to perform operations comprising:

measuring characteristics available to the system, the characteristics including route and non-route related characteristics; and

15 modifying route attributes of an existing route based on the measured characteristic.

88. The machine-readable medium of claim 87 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations further comprising tagging the existing route when a characteristic exceeds a predetermined measurement amount, and  
20 wherein modifying comprises dynamically modifying the route attributes based on the tagging.

89. The machine-readable medium of claim 88 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations, wherein the characteristic includes a traffic statistic  
25 including at least one of either bandwidth or a number of dropped packets of a link.

90. A method of configuring a router comprising:

evaluating a configuration file to determine relationships between route attributes;

expressing the relationships in one or more mathematical functions; and

when a route is received from a customer, modifying the attributes of the

5 received route based on results of the mathematical functions.

91. The method of claim 90 further comprising:

generating a revised configuration file which expresses the relationships between the route attributes with the one or more mathematical functions; and

wherein when the route is received from the customer, modifying

10 comprises modifying the attributes of the received route using the revised configuration file.

92. The method of claim 90 further comprising routing a received packet using the received route with the modified attributes.

93. The method of claim 90 wherein the one or more mathematical  
15 functions comprises at least one of:

adding an offset to a value of a first attribute for a determined value of a second attribute; and

multiplying the value of the first attribute by a factor for the determined value of the second attribute.

20 94. The method of claim 93 wherein the first and second attributes comprise at least two of a community tag attribute, a local preference attribute, and a multi-exit discriminator (MED) attribute, and

wherein evaluating determines relationships between the first attribute and the second attribute of routes in the configuration file, and expressing  
25 comprises generating a mathematical relation between the first and second attributes.

95. A routing system comprising:

a processor to evaluate a configuration file to determine relationships between route attributes and to generate the relationships in one or more mathematical functions; and

- 5 a storage element to store relationships express in the one or more mathematical functions, wherein when a route is received from a customer, the processor is to modify the attributes of the received route based on results of the mathematical functions.

96. The system of claim 95 wherein the storage element is to store a revised configuration file which expresses the relationships between the route  
10 attributes with the one or more mathematical functions.

97. The system of claim 95 wherein the processor is to route a received packet using the received route with the modified attributes.

98. The system of claim 95 wherein the one or more mathematical functions comprises at least one of:

- 15 adding an offset to a value of a first attribute for a determined value of a second attribute; and  
multiplying the value of the first attribute by a factor for the determined value of the second attribute.

99. The system of claim 98 wherein the first and second attributes  
20 comprise at least two of a community tag attribute, a local preference attribute, and a multi-exit discriminator (MED) attribute, and

wherein the processor is to determine relationships between the first attribute and the second attribute of routes in the configuration file, and is to generate a mathematical relation between the first and second attributes.

- 25 100. A system comprising:  
means for evaluating a configuration file to determine relationships between route attributes;

means for expressing the relationships in one or more mathematical functions; and

means for modifying the attributes of a received route based on the mathematical functions.

5           101. The system of claim 100 further comprising:

means for generating a revised configuration file which expresses the relationships between the route attributes with the one or more mathematical functions.

10           102. The system of claim 100 further comprising means for routing a received packet using the received route with the modified attributes.

103. The system of claim 100 wherein the one or more mathematical functions comprises at least one of:

an addition function for adding an offset to a value of a first attribute for a determined value of a second attribute; and

15           a multiplication function for multiplying the value of the first attribute by a factor for the determined value of the second attribute.

104. The system of claim 103 wherein the first and second attributes comprise at least two of a community tag attribute, a local preference attribute, and a multi-exit discriminator (MED) attribute, and

20           wherein the means for evaluating is to determine relationships between the first attribute and the second attribute of routes in the configuration file, and is to generate a mathematical relation between the first and second attributes.

105. A machine-readable medium that provides instructions, which when executed by one or more processors, cause said processors to perform operations comprising:

evaluating a configuration file to determine relationships between route attributes;

expressing the relationships in one or more mathematical functions; and

when a route is received from a customer, modifying the attributes of the received route based on the mathematical functions.

106. The machine-readable medium of claim 105 wherein the instructions, when further executed by one or more of said processors cause said  
5 processors to perform operations further comprising:

generating a revised configuration file which expresses the relationships between the route attributes with the one or more mathematical functions; and

wherein when the route is received from the customer, modifying comprises modifying the attributes of the received route using the revised  
10 configuration file.

107. The machine-readable medium of claim 105 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations further comprising routing a received packet using the received route with the modified attributes, and wherein the one or  
15 more mathematical functions comprises at least one of:

adding an offset to a value of a first attribute for a determined value of a second attribute; and

multiplying the value of the first attribute by a factor for the determined value of the second attribute.

20 108. The machine-readable medium of claim 107 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations, wherein the first and second attributes comprise at least two of a community tag attribute, a local preference attribute, and a multi-exit discriminator (MED) attribute, and

25 wherein evaluating determines relationships between the first attribute and the second attribute of routes in the configuration file, and expressing comprises generating a mathematical relation between the first and second attributes.

109. A method comprising:

applying at least one of a plurality of event triggers to a received route;  
and  
taking a predetermined action when the applying indicates that a  
triggering event occurs.

5           110. The method of claim 109 wherein the predetermined action includes one of limiting a number of routes received from a peer, filtering specific blocks of address space on the peer may be filtered, or logging a message.

111. The method of claim 110 further comprising applying policy to the received route, and wherein the event triggers comprise an extension to language  
10 of the policy.

112. A routing system comprising:  
a storage element to store a plurality of event triggers; and  
a processor to apply at least one of the event triggers to a received route,  
and to take a predetermined action when the applying indicates that a triggering  
15 event occurs.

113. The system of claim 112 wherein the predetermined action includes one of limiting a number of routes received from a peer, filtering specific blocks of address space on the peer may be filtered, or logging a message.

114. The system of claim 113 wherein the processor is to further apply  
20 policy to the received route, and wherein the event triggers comprise an extension to language of the policy.

115. A system comprising:  
means applying at least one of a plurality of event triggers to a received  
route; and  
25 means for taking a predetermined action when the means for applying indicates that a triggering event occurs.

116. The system of claim 115 wherein the predetermined action includes one of limiting a number of routes received from a peer, filtering specific blocks of address space on the peer may be filtered, or logging a message.

117. The system of claim 116 further comprising means for applying  
5 policy to the received route, and wherein the event triggers comprise an extension to language of the policy.

118. A machine-readable medium that provides instructions, which when executed by one or more processors, cause said processors to perform operations comprising:

10       applying at least one of a plurality of event triggers to a received route;  
and  
      taking a predetermined action when the applying indicates that a triggering event occurs.

119. The machine-readable medium of claim 118 wherein the  
15 instructions, when further executed by one or more of said processors cause said processors to perform operations, wherein the predetermined action includes one of limiting a number of routes received from a peer, filtering specific blocks of address space on the peer may be filtered, or logging a message.

120. The machine-readable medium of claim 119 wherein the  
20 instructions, when further executed by one or more of said processors cause said processors to perform operations further comprising applying policy to the received route, and wherein the event triggers comprise an extension to language of the policy.

121. A method of staging routing policies comprising:  
25       applying a staged-routing policy and an existing-routing policy to a received route;  
      updating a routing-information base with results of the applied staged-routing policy and the applied existing-routing policy; and

comparing packet forwarding results of the staged and existing routing policies by applying the updated routing-information base to packets.

122. The method of claim 121 wherein updating comprises marking updates from the applied-staged routing policy in the routing-information base.

5           123. A routing system comprising:

a storage element to store a routing-information base, a staged-routing policy and an existing-routing policy; and

a processor to apply a staged-routing policy and an existing-routing policy to a received route, to update the routing-information base with results of  
10 the applied staged-routing policy and the applied existing-routing policy, and to compare packet forwarding results of the staged and existing routing policies by applying the updated routing-information base to packets.

124. The system of claim 123 wherein the processor is mark updates from the applied-staged routing policy in the routing-information base.

15           125. A system comprising:

means for applying a staged-routing policy and an existing-routing policy to a received route;

means for updating a routing-information base with results of the applied staged-routing policy and the applied existing-routing policy; and

20           means for comparing packet forwarding results of the staged and existing routing policies by applying the updated routing-information base to packets.

126. The system of claim 125 wherein the means for updating further comprises means for marking updates from the applied-staged routing policy in the routing-information base.

25           127. A machine-readable medium that provides instructions, which when executed by one or more processors, cause said processors to perform operations comprising:

applying a staged-routing policy and an existing-routing policy to a received route;

updating a routing-information base with results of the applied staged-routing policy and the applied existing-routing policy; and

5 comparing packet forwarding results of the staged and existing routing policies by applying the updated routing-information base to packets.

128. The machine-readable medium of claim 127 wherein the instructions, when further executed by one or more of said processors cause said processors to perform operations, wherein updating comprises marking updates  
10 from the applied-staged routing policy in the routing-information base.

129. A method of generating routing policy comprising:  
decoupling data items from actions associated with the data items; and  
building a routing policy by combining common components using set operations on the data items and the actions,  
15 wherein common data items that span across more than one domain are reused for the more than one domain,  
wherein the data items comprise prefixes, as-path expressions and community lists, and  
wherein the actions comprise at least accept and deny actions.

20 130. A routing system comprising:  
a plurality of filters that share common data items for reuse across more than one domain; and  
one or more processing elements to decouple data items from actions associated with the data items and to build a routing policy by combining  
25 common components using set operations on the data items and the actions,  
wherein common data items that span across more than one domain are reused for the more than one domain,  
wherein the data items comprise prefixes, as-path expressions and community lists,  
30 wherein the actions comprise at least accept and deny actions, and

wherein the plurality of filters comprise either packet or route filters.

131. A method of generating routing policy comprising:

prefixing statements of a single routing policy with either source or sink designations;

5           applying statements with the source designations to match operations;

and

applying statements with the sink designations to set operations.

132. A routing system comprising:

a single routing policy comprising statements prefixed with either source

10       or sink designations; and

processing elements to apply ones of the statements with the source designations to match operations, and to apply one of the statements with the sink designations to set operations.
